

**MINER ID: sirjan**

**Additional methods in Block class:**

noncegen(): Generates a nonce that can be used to make the hashcode for the block. Sets the nonce value for the block on each call.

blockHashmaker(): calls noncegen() every time it generates a hash code until the desired hashcode with 5 leading zeros is achieved. The last call to noncegen() through which it was possible will set the nonce value to the value that led to the desired hashcode.
